THIS CASE STUDY • 16 PAGES • REAL PAYOUT HISTORY • 2 TRADES BROKEN DOWN • BEFORE AND AFTER

Contents

- 03 What his numbers actually say**
10k plus in the first month, on 1,300 dollars of eval fees
- 04 His win rate, before and after**
30 to 40 percent for real, and the honest gap to what he thinks he left on the table
- 05 Watching the thesis itself change**
from a chart full of random boxes to something a mentor can actually mark up
- 06 One more source of levels**
why a KG1 level mattered when his own high volume nodes weren't nearby
- 07 Trade 1: the red rejection area**
a level, a minor high volume node lined up with it, and a stop above the high
- 08 Trade 2: the expansion leg**
a second tap, absorption at the level, and a thesis that played out bigger than planned
- 09 The risk model neither mentor taught**
trailing convexity, and why a normal breakeven quietly ruins your EV
- 10 Two mentorships, and what neither gave him**
order flow basics from one, strategy from another, habits from neither
- 11 Trading as a business**
the analogy that made data collection non negotiable
- 12 Building a thesis live, on the call**
current auction, price in the AMT cycle, and the one objective that mattered
- 13 The short he wouldn't take anymore**
a level marked, sellers already absorbed, and the trade he used to take anyway
- 14 What he'd tell someone joining tomorrow**
trade the levels, not the middle of nowhere
- 15 The numbers now**
roughly seven times more efficient, by his own account

What his numbers actually say

10k plus, on 1,300 dollars of eval fees

This is a case study built around one question put to a member directly on a call: how did you get to a 10,000 dollar plus month in your first month inside the mentorship. His answer starts with a number most traders never actually check. He spent around 1,300 dollars on evaluation fees that month. Before joining, the same kind of month cost him closer to 7,000 dollars to make 9,000 to 10,000, which is barely a return at all once the eval spend is counted honestly.

PAYOUT HISTORY, FROM HIS OWN DASHBOARD

REQUEST DATE	APPROVAL DATE	AMOUNT	STATUS
Jul 8, 2026	Jul 8, 2026	\$2000.00	PAID
Jun 30, 2026	Jun 30, 2026	\$1845.50	PAID
Jun 23, 2026	Jun 23, 2026	\$1223.75	PAID
Jun 22, 2026	Jun 22, 2026	\$1974.50	PAID

Four payouts from one of his funded accounts, all marked paid. The 10k plus figure he states is across his accounts for that month, this is one dashboard of it, not the whole total, shown because it's real and it's his, not a claim with nothing behind it.

His win rate, before and after

30 to 40 percent, and the honest gap underneath it

Before the mentorship his actual win rate sat around 30 to 40 percent. He's careful about the next number, calling it a guess rather than something he measured: if he'd traded his own model properly, without the impatience, he thinks he would have been running 50 to 60 percent. That gap between the two numbers isn't a strategy problem, by his own account. It's the difference between having a model and actually having the discipline to sit inside it.

His own summary, written mid call: bad reward to risk on his setups, a 30 to 40 percent win rate, no discipline, no conviction. What he says the mentorship actually solved sits right underneath it in green, a mentor reviewing trades and thesis building, not a new indicator.

Watching the thesis itself change

from a chart full of random boxes to something worth marking up

The clearest proof in the whole call isn't a number, it's scrolling back through his own old thesis posts. His first ones are described, on the call, as "so many random boxes," macro commentary with barely any actual auction reasoning behind it. What changed wasn't a new tool, it was a mentor commenting on every single one and him having to answer for it. By his own account that's the part that actually moved his win rate, being made to defend a level in writing before the session, not just after it worked.

How he marks a level now: multiple prior reaction zones held against the current leg, not one box guessed at. This is the same practice the mentorship built, applied on a real chart rather than a screenshot from a lesson.

Thesis reviews like the ones that changed his, run daily inside the mentorship.

One more source of levels

why a KG1 level mattered when nothing else was nearby

Before, his levels came from one place: high volume nodes he'd drawn himself on the higher timeframe, wherever they'd already produced a clean reaction. That works, until price sits nowhere near one of them. On a day like that he used to have nothing to trade off, or worse, he'd trade the middle of the range anyway.

The KG1 level gave him a second, statistically backed source to work from, gamma levels aligned with his own areas of interest. Not a replacement for his own reading, another input into the same thesis. More levels with real data behind them meant more high conviction setups instead of forcing a trade because a session felt empty.

Trade 1: the red rejection area

a level, a minor high volume node, a stop above the high

Both trades on this call came from the same pre session work: levels marked out from his own thesis building and profile framing, before a single order went out. The first was a short off a level he'd already marked as a key area of resistance, price had rejected from it before. He lined it up against a minor high volume node sitting close by, two independent reasons pointing at the same price rather than one.

Stop went above the high of the rejection, target set at 1.5R. Nothing exotic in the mechanics, the discipline is entirely in the level selection: he took this because two things agreed, not because price simply arrived somewhere round.

The short marked against the resistance he'd already flagged. Risk above the high in red, the planned reward below it in green.

Trade 2: the expansion leg

a second tap, absorption, and a thesis that outran its own target

Going into the session he'd also written down a second possibility: if price retraced, there was room for a bigger move higher, a backtest of the same structure from the other side. When price came back down to that level and he saw absorption there, buyers stepping in and holding, he took the long. Same 1.5R target as the first trade, same process, same discipline of only acting once the level actually printed the reaction he'd written down beforehand.

What happened next wasn't part of the plan. The move expanded well past the 1.5R target on its own, an outcome he credits to the setup being right, not to predicting the size of the leg in advance. The target was 1.5R. The market gave him considerably more, which is a different thing from having called it.

The long, entered on absorption at the level. The green zone marks how far the actual move ran past the original plan.

This is what a level worth trading actually looks like before and after. Live sessions walk the same read in real time.

The risk model neither mentor taught

trailing convexity, and why a normal breakeven quietly ruins your EV

Asked what he'd never seen anywhere else, he doesn't point at a setup, he points at the risk model: trailing convexity as a way to move a trade to breakeven. His own words on it: it was the first time he'd ever seen anyone actually use it that way.

"If you go normally to breakeven, after a hundred trades, if you actually look at the stats it ruins your EV in a problem environment. But the way you cater it, it's a much better way to go breakeven."

The mechanism itself is taught live inside the mentorship rather than summarised here, this document is his account of what it changed for him, not a replacement for learning it properly. What matters for this case study is the honest framing he uses around it: most traders move to breakeven on instinct, assume it's automatically the safe choice, and never check what it does to their expectancy over a real sample. He hadn't either, until this was shown to him.

Two mentorships, and what neither gave him

order flow from one, strategy from another, habits from neither

He'd been in two prior mentorships before this one. The first taught him most of his order flow basics, reading confirmations, absorption, CVD divergence. The second taught him a scalping strategy. Both are, in his own words, real skills he still uses. Neither one taught him what to do with a losing trade in the moment it stopped looking clean.

His description of trading before this mentorship: he'd see a valid order flow signal, take it, and then panic the instant it didn't play out immediately, moving his stop, moving his target, second guessing a read he genuinely had right. He knew the confluences. He didn't have the conviction to sit inside a trade once it stopped feeling comfortable, because nothing was backing that conviction with data.

HIS OWN FRAMING

Beginner order flow traders lose to what looks like a psychology problem, when it's actually a risk management problem. A framework that tells you exactly where to trail, where to take partials, where to go breakeven removes the decision a panicking trader makes badly in the moment. It isn't a mindset fix, it's a rule that makes the mindset irrelevant.

Trading as a business

the analogy that made data collection non negotiable

The line that reframed everything for him is the same one used throughout the mentorship: trading is a business, and every trade is capital you're putting into it. If you were handing money to an actual business and it couldn't show you its expected value, its return on capital, any stats at all, you wouldn't invest. An index fund can tell you its average return is 8 to 10 percent with a roughly one in fifteen year down year. A trader putting real money into evals, into his own account, into his own trading, usually can't tell you any of that about himself.

"Before you put any money in to invest in yourself into trading, into buying problems, into doing that stuff, you need to have data backing it. Otherwise there's no point."

He says this is what changed his own relationship to a losing trade. Once he had a real sample behind his levels, a loss stopped being a reason to panic and became a data point his own stats already expected. That's the shift he keeps coming back to on the call: not more confidence from hoping harder, confidence built on a number he can actually point to.

Building a thesis live, on the call

current auction, price in the AMT cycle, one objective

Asked to just build a thesis on whatever price was doing at that moment, in real time, this is the order he actually works in. First, what the current auction is doing: an imbalance had just printed a large move up, and price was starting to find a new area of balance. Second, whether price has reacted at this level before, looking left on the chart, which tells him whether the area is a real key level or a fresh one nobody's tested yet.

From there the objective: trading back toward balance, targeting a higher timeframe high volume node, the point of control on the yearly chart in this case. Because the move up had been large, he also expected a retrace or two before that target, and said so before price had done it, which is the actual test of a thesis, stating the expectation first rather than narrating it afterward.

The area he marks red live on the call: a level with a prior reaction behind it, not a line drawn because price happened to be nearby.

The short he wouldn't take anymore

a level marked, sellers already absorbed, and the old trade anyway

He walks through a real example of the kind of short he used to take, back when a valid looking order flow confirmation was enough on its own. Reacting purely off confirmations without the higher timeframe context meant taking trades against a direction that was already telling on itself. Nowadays, seeing a key demand level get tested and sellers absorbed there tells him the higher timeframe bias, and a short like this one doesn't get taken at all, regardless of how clean the local order flow looks.

The pattern he used to trade: repeated short entries fought against a level that kept holding. Same setup, three attempts, the higher timeframe never agreed with any of them. Zoomed out, that same resistance area had sat untouched for two weeks before this leg, and once it finally broke, everything below it stopped being a place to sell from, a read the local chart alone never gave him.

What he'd tell someone joining tomorrow

trade the levels, not the middle of nowhere

Asked directly what he'd focus on in his first month if he joined again tomorrow, his answer wasn't a concept, it was a habit: trading only off marked levels, not in the middle of the range because a chart looks interesting there. Profile framing itself he considers learnable by most people who put the reps in. Actually waiting for a marked level to get hit, doing nothing until it does, was the part he personally struggled with.

HIS OWN CHECKLIST, AS HE DESCRIBED USING IT NOW

What the market is doing right now. What the market wants to do. Where his levels actually are. Where he should trade off them. Nothing on that list is new information, he says, it's the same four questions asked in the same order, every single session, until asking them stopped being optional.

The numbers now

roughly seven times more efficient, by his own account

The exact figure gets a little rounded on the call itself, he corrects himself mid sentence between 1.3 and 1.6 thousand dollars, so treat it as a range rather than a precise number. What's consistent across both figures he gives is the shape of the change: from roughly 7,000 dollars spent to make 9,000 to 10,000 before the mentorship, to somewhere around 1,300 to 1,600 dollars spent to make around 11,000 in a recent month since. Same rough profit, a fraction of the capital it used to cost him to get there.

His own description of what actually changed matches everything earlier in this document: "it's just been more of a disciplined shift and being able to actually follow my habits." Not a new strategy replacing an old one. The same read, executed by someone who finally trusted it enough to stop interfering with it mid trade.

One student. A thesis that finally held up.

Nothing in this case study is a promise about what joining does for you specifically. It's one member's account of what changed for him: a mentor reviewing his thesis daily, a second source of statistically backed levels, and a risk model that made breakeven stop quietly costing him money over a real sample. The work underneath it, the reps, the discipline to wait for a level, was still his.
