The account and the session

the MFFU series, and why not being eligible yet is part of the point

This is a recap of a live AM session on a MyFundedFutures funded account, the first in a series that follows one account from a fresh evaluation pass through to its first payout request. He runs at least three live sessions a week for the mentorship, and this is one of them, unedited: the thesis before a single order went out, then the two trades that came from it.

Where the account actually stood going into this session, payout requirements and the calendar together. Not eligible yet, on purpose shown here rather than skipped: two days since the first trade against a 14 day wait, the buffer still short of the requirement, and the losing day sitting right next to this one. The series is the process, not just the highlight.

Reading an all time high environment

sellers failing to reclaim control, and why the objective was neutral

Going into the session, price had already made a strong move higher, and the read started with what sellers had failed to do: repeated attempts to reclaim the prior range, and repeated failure. The weekly delta profile showed heavy buying aggression behind the move, which is a different statement than "price is going up." It's a statement about who is actually in control of the auction, not just which way the last few candles printed.

The grind higher this session's thesis was built against. Multiple failed attempts to reclaim the range below, each one adding to the case that buyers were priced in, not just leading.

The objective going in was deliberately neutral. In a genuine all time high environment the correct approach is to wait for the pullback and trade within the directional push, not to predict a target in advance. Marrying a bias before the auction has given you structure is exactly the psychological trap this thesis process is built to avoid, reacting to where buyers and sellers should have control rather than guessing where price will land.

The entry signal

a 350 percent divergence box, and an origin of the move entry

The actual trigger was a tool that flags a specific condition: a 350 percent divergence between buying and selling aggression alongside a small imbalance, printed automatically as a green box when it fires. It is not a signal on its own, it is a flag that something worth looking at just happened, passive absorption on one side and aggressive pressure on the other, at the same price.

The setup the box flagged: sellers exhausted, buyers priced in, entered as an origin of the move long once sellers who had been rewarded at this level earlier failed to hold it a second time.

The higher timeframe context mattered as much as the local signal. Zooming out, this level was where sellers had previously been trapped on the way up, visible in the delta profile as buying aggression getting covered rather than reversed. That combination, a local divergence signal sitting inside a higher timeframe area where the opposing side was already known to be weak, is what separated this from a random entry on a green box alone.

Reading real absorption, not just a level that held before

what the CVD was actually doing under an entire session

A beginner reason for drawing a level is "price reacted here before." That's where most thesis building stops, and it's also where it should really start. The example used here is a level from a separate session, the one behind an earlier \$18,000 payout request: a resistance area that had been used, and dumped from, multiple times.

"Price rising = high conviction that session sellers had insane control."

Looking only at price, that resistance area looks like normal supply. Looking at the CVD underneath it tells a different story: across the entire consolidation session, CVD was dying while price held or drifted up, meaning the passive limits at that level were being consumed and reloaded, not defended for free. That combination, price refusing to drop while the delta record shows no real selling pressure behind the level, is what extreme absorption actually looks like, and it's the difference between "this level worked before" and "this level is currently being tested and passed."

The level in question, with the read marked on it live: price grinding up against resistance is not weakness in the level, if the order flow underneath shows sellers being absorbed rather than actually selling.

Trade 1, live: the long

protected low trailing and a higher timeframe target

The first trade recorded live was a long, entered once price showed the strength to push through a short term microbalance. Management was mechanical from there: once the position moved favourably, the stop trailed to the most recent protected low rather than a fixed distance, so the trade could only give back a defined amount of what it had already earned.

The long entry, R:R 5.59 planned against a stop below the microbalance low that formed the entry.

Target was set at a higher timeframe level rather than a fixed tick count, the same discipline as every other level in this document: react to structure that already exists, don't invent a round number to aim at.

Trade 1: trailing to target

recovering yesterday's loss, plus the 500 left on the table

Going in, this trade needed to do two things: recover a loss carried from the prior session, and add the 500 dollars left on the table the day before, when he chose not to trade the PM session at all. It hit target, both conditions met, protected low trailing intact the whole way there.

Trailing into the target. The stop only ever moves toward protecting what the trade has already made, never further into risk.

09 Trade 2, live: the short

a target capped by consistency rules, and the session's last trade

The second live trade was a short, entered on a lower push after the same kind of microbalance read as the first trade, this time working in the opposite direction. The target here was deliberately smaller than the setup alone would have called for, capped by a funded account consistency rule: a prop firm payout requirement that no single day can represent too large a share of total profit, which means sizing the plan to the account's rules, not just to the chart.

The short, same mechanical management as the first trade: trail to protected structure, no fixed target beyond what the account's own consistency rule allowed for the day.

This trade closed the session. Once it hit, the account was up 1.3k for the day off these two trades, and the call there was simple: done for the day, not because the setups stopped, because the plan for the session was already complete.

10 The numbers

+\$2,345 across 5 trades, and what the calendar actually shows

The account's own calendar for the day this session was recorded shows +\$2,345 across 5 trades, against a -\$558 day the session before it. Net P&L across that stretch sits at +\$1,787. Both numbers are shown here directly off the account, not restated from memory, because a funded account series that only ever shows the green days isn't actually showing the process.

The account's own calendar. A losing day, immediately followed by this session, both counted.

He runs live sessions like this one at least three times a week inside the mentorship, voice chat open the whole time, thesis posted before the first trade goes out. This is what that actually looks like end to end: not a highlight of the win, the full process that produced it.

Live sessions like this one, three times a week, thesis posted before the first trade.

JOIN THE ETHOS LIFETIME

whop.com/ethos-orderflow/ethos-lifetime-cb

One session. The thesis, then the two trades it produced.

Nothing here is a promise about what a session looks like on any other day, a losing day sits right next to this one on the same calendar. What's repeatable is the process: read the auction before a single order goes out, react to what it actually shows instead of predicting a target, and manage risk the same mechanical way regardless of which way the trade goes.

If reading it written down was useful, watching it happen is the next step. Sessions run live at least three times a week, the thesis goes up before the first order, and you can sit in on one before deciding whether any of this is for you.

Come and watch a live session first. No pitch, just the read as it happens, and you can leave whenever you want.

The absorption read on page six is the one worth rereading, it's the difference between a level that worked before and a level that's actually being tested right now.

Ethos Order Flow is an educational community. Nothing in this document or inside Ethos is financial advice, a solicitation, or a promise of profit. Futures trading carries substantial risk of loss and is not suitable for every person. The account figures in this document are shown directly from the trader's own funded account, and past results do not guarantee future performance.
